Review of telephone follow-up of women having early medical abortion

Dr Lucy Michie
Chalmers Sexual Health Centre
Introduction

- Increasing numbers of women opt for early medical abortion (≤9 weeks gestation) and choose to go home to pass pregnancy.
- Follow-up required to exclude an ongoing pregnancy.
- Ultrasound involves an extra clinic visit and a high proportion of these women will fail to attend.
- Lead to un-necessary intervention for clinically unimportant RPOC.
- Extra visit may deter women from medical method.
An alternative method - telephone follow-up.

- Pilot study of >450 women in Edinburgh.
- Telephone follow-up at 2 weeks & self-test Low Sensitivity Urine Pregnancy Test (LSUP)
- Questions symptoms, bleeding, LSUP result
- 87% contacted
- 15% (n=60) screened ‘positive’ 3 ongoing preg
- NPV 99.7% (95% CI 98.4-99.9)

Cameron et al Contra 2012
Aims and Methods

- Is telephone follow-up to detect ongoing pregnancy still an effective method of follow-up a year on from its introduction?
- All women having early medical abortion (≤9 weeks) and going home to pass pregnancy, over 12 month period (March 2011 – February 2012).
  - Retrospective computerized database review.
  - Regional maternity database checked.
Results - Demographics

- 78% of abortions (1698 of 2180 total) in Edinburgh are medical abortions ≤9wks gestation.
- 64% (1084) of women opted to go home to pass pregnancy following administration of misoprostol.
  - Mean age 25 years.
  - 31% previous abortion.
  - 56% ≤7wks gestation.
No telephone follow-up necessary (n=125)

- 3 - complete abortion confirmed in hospital.
- 112 – chose clinic follow-up. No ongoing pregnancies.
- 10 (1%) - of 969 – had an unscheduled clinic visit due to pain and/or bleeding.
  - 1 ongoing pregnancy
Outcome of telephone follow-up (n=959)

- **Contacted (n=656) 68%**
  - Screen positive (n=83)
    - 13%
    - 3 ongoing pregnancies
  - Screen negative (n=573)
    - 87%
    - No ongoing pregnancies

- **Not contacted (n=303) 32%**
  - Lost to follow-up (n=59)
    - No ongoing pregnancies
  - No response after x3 calls (n=244)
    - 2 ongoing pregnancies
No telephone contact (n = 303, 32%)

- wrong/no number
- no longer in area
- No ongoing pregnancies.

- 2 ongoing pregnancies at 12+wks and 20+wks.

Not contacted (n=303)

- No contact made (n=59)
- No response after X3 calls (n=244)
Screen positive (n=83, 13% of women contacted)

- ≤3 days bleeding
- OR
- ongoing symptoms
- OR
- positive/equivocal LSUP
- OR
- lost test

- No ongoing pregnancy (n=36, 43%)
- Incomplete (n=1, 1%)
- Repeat test negative (n=10, 12%)
- Ongoing pregnancy (n=3, 4%)

Lost to follow-up
No ongoing pregnancy (n=33, 40%)
Conclusion
How good is telephone follow-up?

- Follow-up in 68%
  - significantly lower than in previous pilot study (87%)
    - $p < 0.0001$
  - similar to follow-up with clinic visit
- No false negative screens identified.
- 13% (n=83) screened positive, 3 ongoing pregnancies.
- Sensitivity of 100%, Specificity of 88% (95% CI 84.9-90.1)
- NPV - 100% (95%CI 99.1-100)

- Effective and alternative method of follow-up.
- Other abortion services should consider this in women having early medical abortion.
